

## New Zealand Hoki

New Zealand hoki is a fast-growing fish that can grow up to 1.3 metres long. Hoki are found in waters around New Zealand and occur in greatest abundance at depths of 200 to 800 metres. They reach adulthood in 3-5 years and can live for up to 25 years.

Hoki fishing takes place at several fishing grounds around New Zealand including the Stewart-Snares shelf south of Stewart Island, the Sub-Antarctic, the west coast of the South Island, Cook Strait, and the Chatham Rise east of the South Island (see map on next page).

The hoki fishery consists of an eastern stock and a western stock. Scientific research is carried out on both stocks and separate catch limits apply to the eastern and western stocks as part of the overall catch limit set annually by the Minister of Fisheries.

### How do we manage our hoki fish stocks?

New Zealand's hoki fisheries are managed using the best available scientific research. This research is carefully reviewed by expert scientists, with active participation by fisheries managers and representatives of environmental and commercial fishing interests.

Each year scientists estimate the number of hoki in each stock. Because hoki grow and reproduce quickly, these numbers can change a lot from year to year. How many young hoki reach adulthood from one year to the next is one of the factors involved in this variation. Other factors include changes in water temperature as well as the numbers of fish caught in previous years.

Fluctuations in the number of hoki are taken into account when decisions are made on setting catch limits, to make sure the fishery is sustainable over the long term. Reducing or increasing catch limits in

response to changes in the numbers of fish is a sign that a fishery is being well managed.

Between 2001 and 2007 hoki catch limits were cut from 250,000 tonnes to 90,000 tonnes because there was a significant reduction in the number of young fish reaching adulthood. This is believed to have been largely caused by environmental conditions.

Four large areas of New Zealand waters are voluntarily closed to hoki fishing. These hoki management areas (HMAs) are important nursery grounds for young fish and protecting them ensures more young fish will survive to adulthood and be able to breed.

Scientific research showed that as of 2009, both hoki stocks had fully rebuilt to target levels, and could sustainably support increased catches. Based on this information several increases to the hoki catch limits were made between 2009 and 2014, increasing them from 90,000 tonnes to 160,000 tonnes. Catch limits were reduced to 150,000 tonnes in 2015/16 and did not change in 2016/17.

### How do we know the hoki fisheries are being sustainably managed?

An independent certifying body, the internationally recognised Marine Stewardship Council (MSC), has certified both New Zealand hoki stocks as being sustainably managed. In 2001, hoki was the first fishery in New Zealand – and one of the first in the world – to achieve MSC certification. Certification lasts for five years, and the fishery was re-certified in

2007 and again in 2012. In September 2018, several hoki, hake and ling fisheries were recertified by the MSC, and are now referred to as the New Zealand Hoki, Hake and Ling Trawl Fishery.

### How do we ensure that hoki fishing does not damage the marine environment?

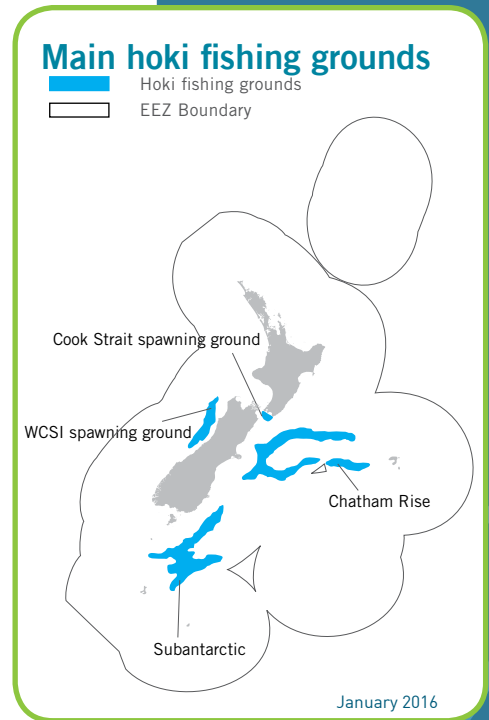

Fishing, like any human activity, almost always has an impact on the environment. Fisheries New Zealand monitors hoki fishing to ensure this impact stays within acceptable levels. If this is not the case, Fisheries New Zealand works closely with the fishing industry to alter fishing practices so that impacts are reduced.

Hoki fishing boats are known to accidentally catch protected seabirds such as albatrosses and petrels. Fishers on larger vessels (greater than 28m long) are legally required to take measures to avoid harming seabirds, such as using bird-scaring devices to keep birds away from the fishing gear where they can get caught. Fishers must also be careful about both the amount and type of fish waste that is returned to the water, because this can attract seabirds to the boat.

In 2017, Fisheries New Zealand assessed the risk to seabirds from commercial fisheries and found that the hoki fishery contributed to four seabird species being classified as “medium risk” or above. The fishing industry and Fisheries New Zealand are continuing to work collaboratively on ways to ensure a continual reduction in the capture rate of seabirds.

New Zealand fur seals are also accidentally caught in fishing gear when they try to eat fish caught in the nets. The fishing industry, with government support, has developed guidelines for both larger and smaller hoki fishing vessels to reduce the risk of accidentally catching fur seals.

Some fishing vessels use bottom trawling nets to catch hoki. However, Fisheries New Zealand monitors bottom trawling carefully and, with support from the fishing industry, has closed large areas of New Zealand waters to bottom trawling. More about these closures can be found in the information sheet “Protecting New Zealand’s seabed from the impacts of bottom trawling”.

#### Did you know:

- The value of hoki quota in 2016 was approximately \$1,025 million.
- Hoki is New Zealand's largest fishery, with around 59,000 tonnes of processed fish exported in 2017.
- In 2017, hoki exports contributed more than \$228 million to the New Zealand economy.
- Hoki is exported all over the world – including Australia, China, Europe and the United States.

This information provides a high-level overview of an aspect of the New Zealand fisheries management regime.
