## EXECUTIVE SUMMARY

**Horn, P.L.; Sutton, C.P. (2019). Catch-at-age for hake (*Merluccius australis*) and ling (*Genypterus blacodes*) in the 2017–18 fishing year and from research trawl surveys in 2018, with a summary of all available data sets from the New Zealand EEZ.**

*New Zealand Fisheries Assessment Report 2019/63. 81 p.*

This report describes catch-at-age distributions for hake (*Merluccius australis*) and ling (*Genypterus blacodes*) estimated from commercial fisheries for these species in the 2017–18 fishing year using data and otoliths collected at sea by observers, and from research trawl surveys of middle depth species off the west coast South Island in August 2018 (TAN1807) and in the Sub-Antarctic in December 2018 (TAN1811). The target coefficient of variation (CV) for each estimated catch-at-age distribution from the observer samples and the trawl survey was 30% (mean weighted CV across all age classes).

For hake, the target CV was met for two commercial fisheries (west coast South Island, and Sub-Antarctic), but there were insufficient data to estimate catch-at-age for either the eastern or western Chatham Rise commercial trawl fishery. Catch-at-age for the August 2018 trawl survey of west coast South Island was also estimated, but the estimated CV (60%) exceeded the target CV. The catch-at-age for the December 2018 trawl survey of the Sub-Antarctic had an estimated CV of 52% which also did not meet the target.

For ling, the target CV was met for the commercial trawl fisheries from west coast South Island, Chatham Rise, and the Sub-Antarctic, and for the December 2018 Sub-Antarctic trawl survey, but not for the August 2018 west coast South Island trawl survey. There were insufficient data collected to estimate catch-at-age for the 2018 Cook Strait commercial trawl fishery. Catch-at-age was also estimated, and the target CVs were met for the ling longline fisheries on Chatham Rise and the Campbell Plateau in 2017–18.

Where target CVs were not met, it was not possible to improve the precision by reading more otoliths (i.e., increasing the sample size), because all available data and otoliths were used in the analyses. We recommend that observer sampling for ling and hake is focused on areas and months needed for existing catch-at-age time-series. Those areas and months are listed in the last paragraph of the Discussion in this document. Summaries of all previous catch-at-age distributions made for hake and ling from trawl surveys and commercial fisheries are also provided.

It is recommended that all future analyses of commercial fishery catch-at-age include an evaluation of the representativeness of the observer sampling (as presented in Appendix C for west coast South Island hake).

## **1. INTRODUCTION**

This work aimed to determine catch-at-age from the main fisheries for hake and ling in the 2017–18 fishing year, and for hake and ling from research trawl surveys conducted in August and December 2018. Catch-at-age data are a vital input for the stock assessment process as they provide important information on the year class strength of recruited cohorts, and enable calculation of selectivity ogives for the trawl surveys and commercial fisheries for these species. This report describes the resulting catch-at-age distributions for hake and ling; the new data extended existing series of catch-at-age data. It fulfils the reporting requirements for hake and ling in Objective 1 of Project MID201803 “Routine age determination of hoki and middle depth species from commercial fisheries and trawl surveys”, funded by the Ministry for Primary Industries. That objective is:

1. To determine catch-at-age for commercial catches and resource surveys of specified middle depth and deepwater fishstocks.

The report also summarises all historic catch-at-age data sets for hake and ling from trawl surveys and commercial fisheries, and describes the strata used in the analyses of data from the commercial trawl fisheries. The derivation of the strata was presented by Horn & Sutton (2008), although the Chatham Rise hake strata were modified in 2010 (Horn & Francis 2010).

## **2. METHODS**

For hake, it was proposed to age the following samples (with the approximate number of otoliths to be aged in square brackets):

HAK 1 — commercial trawl fishery, east and south of South Island, Sep 2017–May 2018 [650].  
HAK 1 — research trawl survey, Sub-Antarctic, December 2018 (project MID2018-01) [650].  
HAK 4 — commercial trawl fishery, east Chatham Rise, Oct 2017–Apr 2018 [650].  
HAK 7 — commercial trawl fishery, west coast South Island (WCSI), Jun–Sep 2018 [650].  
HAK 7 — research trawl survey, WCSI, August 2018 (project MID2018-02) [650].

For ling, it was proposed to age the following samples (with the number of aged otoliths in square brackets):

LIN 3&4 — commercial longline fishery, Chatham Rise, Jun–Oct 2017 [550].  
LIN 3&4 — commercial trawl fishery, Chatham Rise, Oct 2017–May 2018 [600].  
LIN 5&6 — commercial longline fishery, spawning, Puysegur, Oct–Dec 2016, and non-spawning, Campbell, Feb–Jul 2017 [500 per fishery].  
LIN 5&6 — research trawl survey, Sub-Antarctic, December 2018 (project MID2018-01) [600].  
LIN 7 — research trawl survey, WCSI, August 2018 (project MID2018-02) [600].  
LIN 7&2 — commercial trawl fishery, Cook Strait, Jun–Sep 2017 [500].

There was insufficient data available from the Chatham Rise (HAK 4) trawl fishery, and insufficient or no observer otoliths available from the ling longline spawning fishery on Sub-Antarctic (LIN 5&6), and the winter 2018 Cook Strait trawl fishery (LIN 7&2), so catch-at-age distributions were not able to be produced for those fisheries.

The following additional commercial fishery catch-at-age distributions for ling were estimated using age-length keys derived previously from either the January 2018 Chatham Rise research trawl survey (LIN 3&4) or the August 2018 WCSI research trawl survey (LIN 7), with the addition of some extra observer-collected otoliths to cover lengths that were not adequately sampled by the trawl surveys.

LIN 3&4 — commercial trawl fishery, Chatham Rise, Oct 2017–May 2018.  
LIN 7 — commercial trawl fishery, WCSI, Jun–Sep 2018.

A catch-at-age model describing the age structure of each of the commercial fisheries and surveyed areas was developed as in previous years (most recently by Horn & Sutton 2019) for both species. For each of the samples, otoliths (for each sex separately) from each 1 cm length class were selected roughly in proportion to their occurrence in the scaled length frequency, with the constraint that the number of otoliths in each length class (where available) was at least one. In addition, all otoliths from fish in the extreme right hand tail of the scaled length frequency distribution (constituting about 2% of that length frequency) were fully sampled. Any clear juvenile length modes were deliberately under-sampled (usually taking only 2–3 otoliths per length class), as these modes could comprise large numbers of similarly aged young fish. This sampling procedure was likely to provide a sample with a mean weighted CV better than that from proportional sampling, particularly for the older age classes. Otoliths were prepared and read using the validated ageing technique for hake (Horn 1997) or ling (Horn 1993). Catch-at-age was calculated by constructing age-length keys separately for each sex and applying them to the scaled length frequency data derived from each fishery or survey separately using software developed specifically for this task by NIWA (Bull & Dunn 2002).

Commercial fishery catch-at-age distributions were scaled to the total estimated catch from each fishery in the time period sampled. For fisheries with multiple strata, length frequency data from each stratum were first scaled to the estimated catch from that stratum, and then the length frequencies from all strata were summed, and the resulting age-length key was applied to the total length frequency. Trawl survey catch-at-age distributions were scaled to total estimated relative biomass available to the trawl in the survey area.

In some instances, trawl surveys occurred around the middle of the periods sampled for commercial fishery catch-at-age (e.g., the January Chatham Rise trawl survey occurred in the middle of the October–April hake trawl fishery and the October–May ling trawl fishery). Consequently, where a survey occurred during a fishery, catch-at-age distributions for the fisheries were estimated using age-length keys developed for the relevant survey. It was sometimes necessary, however, to age some additional fish from the trawl fisheries to cover length-sex combinations that were inadequately sampled by the survey. Such additional samples seldom comprised more than 150 otoliths.

The target mean weighted CV for hake from trawl surveys was often not met. To maximise the chances of meeting the target, all hake from the trawl shots used for survey biomass and scaled length-frequency calculations were measured and their otoliths were collected. Any hake caught in survey tows not used for biomass calculations (i.e., foul shots, midwater tows, or night tows) were also sampled. These extra fish were aged, and the data incorporated into the age-length key. Consequently, in the data summaries shown below, the number of aged hake from the trawl surveys is often greater than the number of measured fish (i.e., the fish used to calculate the catch-at-length and catch-at-age).

### 3. RESULTS

#### 3.1 Observer catch-at-age data from hake trawl fisheries

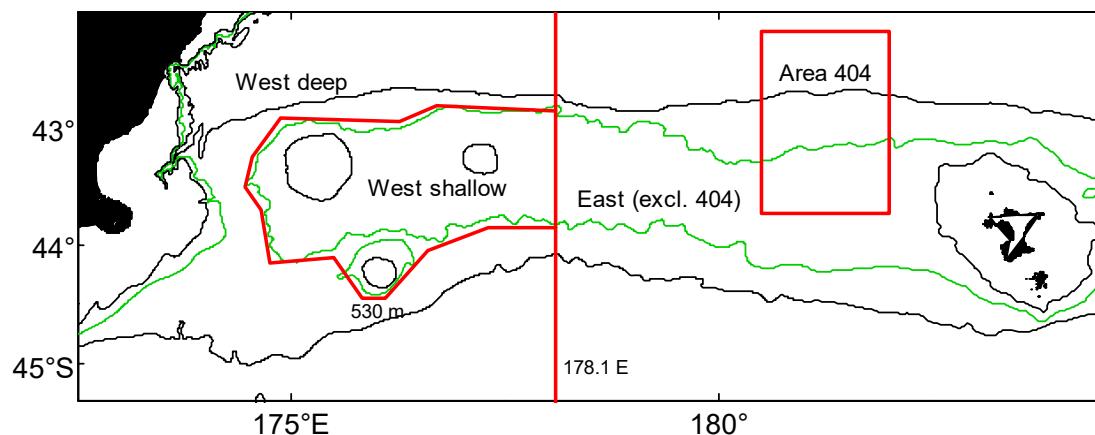

##### 3.1.1 Chatham Rise

Data from the Chatham Rise were previously analysed as four separate fisheries (e.g., Horn & Sutton 2009) as shown in Figure 1, and defined as follows:

1. West shallow (longitude  $\leq 178.1^\circ$  E, and bottom depth  $\leq 530$  m).
2. West deep (longitude  $\leq 178.1^\circ$  E, and bottom depth  $> 530$  m).
3. East excl. area 404 (longitude  $> 178.1^\circ$  E, excluding Statistical Area 404).
4. Area 404 ( $178^\circ$  W  $\leq$  longitude  $\leq 179.5^\circ$  W,  $42^\circ$  S  $\leq$  latitude  $\leq 43.75^\circ$  S).

An assessment of the Chatham Rise hake stock (Horn & Francis 2010) concluded that splitting the data into two fisheries (i.e., west and east, each with two strata), rather than four fisheries was statistically satisfactory. Consequently, two commercial age frequencies have been developed for each year since the start of this series (whenever sufficient data were available) using a single age-length key and two areas separated at longitude  $178.1^\circ$  E. The raw data were still stratified as shown in Figure 1, so each fishery comprised two strata. A single age-length key for each year was used, as Horn & Dunn (2007) showed that mean age-at-length did not differ between fisheries (i.e., in years when there were sufficient data to estimate catch-at-age for both fisheries, the same age-length key was used for both).

A tow was included in the catch-at-age analysis if it occurred between 1 October and 30 April, and if at least five hake were measured from it.

**Figure 1: Strata defined for the Chatham Rise hake fishery. The west stratum boundary defined by depth (530 m) is shown only approximately (red). Isobaths at 1000 (black), 500 (green), and 250 m (black) are also shown.**

Observer data from each fishery were converted into catch-at-age distributions if there were at least 400 length measurements (west fishery) or 300 length measurements (east fishery). Table 1 summarises the quantities of useful data. In the 2017–18 fishing year, insufficient length data were available from both the western ( $n = 143$ ) and eastern ( $n = 183$ ) strata to calculate catch-at-age distributions, and only 99 otoliths were collected.

Estimated proportion-at-age distributions for all years from the two Chatham Rise trawl fisheries are presented in Appendix A (Figures A1 and A2).

**Table 1: Numbers of measured (by fishery) and aged (fisheries combined) male (M) and female (F) hake contributing to samples of proportion-at-age from the two commercial trawl fisheries on the Chatham Rise from 1991–92 to 2017–18. The number of tows sampled by observers and the estimated mean weighted CV (%) by age are also listed. Values in italics (and where Tows and CV columns are blank) indicate that insufficient length-frequency data were available to allow estimation of catch-at-age.**

### 3.1.2 Sub-Antarctic

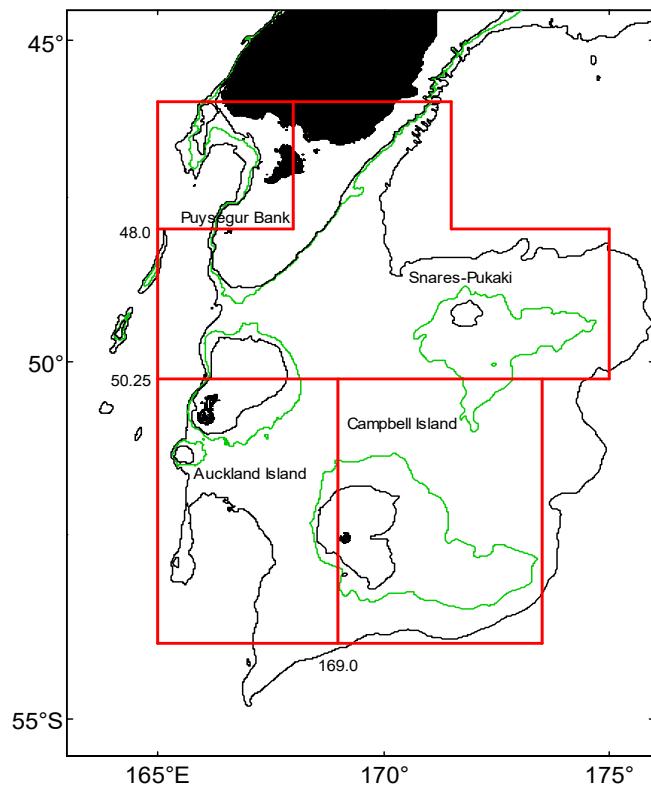

There was one major and three very minor hake fisheries in the Sub-Antarctic area, so a single fishery ogive was used in assessments of this stock. A commercial age frequency was developed using a single age-length key and the four fishery strata shown in Figure 2 (determined by Horn (2008b)), and defined as follows:

1. Puysegur Bank ( $165^{\circ}$  E  $\leq$  longitude  $\leq 168^{\circ}$  E,  $46^{\circ}$  S  $\leq$  latitude  $\leq 48^{\circ}$  S).
2. Snares-Pukaki ( $165^{\circ}$  E  $\leq$  longitude  $\leq 175^{\circ}$  E,  $46^{\circ}$  S  $\leq$  latitude  $\leq 50.25^{\circ}$  S, but excluding the Puysegur Bank stratum and the area north of  $48^{\circ}$  S and east of  $171.6^{\circ}$ ).
3. Auckland Island ( $165^{\circ}$  E  $\leq$  longitude  $\leq 169^{\circ}$  E,  $50.25^{\circ}$  S  $<$  latitude  $\leq 54^{\circ}$  S).
4. Campbell Island ( $169^{\circ}$  E  $<$  longitude  $\leq 174^{\circ}$  E,  $50.25^{\circ}$  S  $<$  latitude  $\leq 54^{\circ}$  S).

A tow was included in the catch-at-age analysis if it occurred between 1 September and 31 March, and if at least five hake were measured from that tow. The time stratum was based on a descriptive analysis indicating a landings peak from September to February (Devine 2008), so it is not logical to use the administrative fishing year (1 October to 30 September) which bisects the fishery timing. Observer data were converted into catch-at-age distributions if there were at least 700 length measurements, and if there were sufficient otoliths ( $n$  about 400) to produce a comprehensive age-length key.

Table 2 summarises the data used each year to produce the catch-at-age distributions, and the resulting mean weighted CVs. Details of the estimated catch-at-age distribution for trawl-caught hake in the 2017–18 fishing year are in Table 3. The mean weighted CV of 22% was lower than the target of 30%.

All estimated proportion-at-age distributions from the Sub-Antarctic trawl fishery are presented in Appendix A (Figure A3).

**Figure 2: Fishery strata defined for the Sub-Antarctic hake fishery (red lines). Numbers show latitudes and longitudes of fishery boundaries. Isobaths at 1000 (black), 500 (green), and 250 (black) m are also shown.**

**Table 2: Numbers of measured male and female hake, numbers of fish aged and used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Sub-Antarctic trawl fishery. –, no data.**

### 3.1.3 West coast South Island (WCSI)

The fishery off WCSI was stratified (by Horn & Sutton (2008)) as follows:

1. Deep (bottom depth  $\geq 629$  m).
2. North shallow (bottom depth  $< 629$  m, latitude  $< 42.55^\circ$  S).
3. South shallow (bottom depth  $< 629$  m, latitude  $\geq 42.55^\circ$  S).

A tow was included in the catch-at-age analysis if it occurred between 1 June and 30 September, and if at least five hake were measured from that tow.

Table 4 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The HAK 7 stock was assessed in early 2019 and the Deepwater Fisheries Assessment Working Group queried whether the observer sampling was representative of the fishery. Consequently, an analysis was conducted here to establish whether the sampling of hake from WCSI was adequate (Appendix C). Estimated landings of hake from the WCSI stock area were compared with landings sampled for hake by observers; it was concluded that observer sampling of the hake fishery in 2017–18 (and in most previous years) was comprehensive. It is recommended that all future analyses of commercial fishery catch-at-age (for both hake and ling in all areas) include an evaluation of the representativeness of the observer sampling.

Details of the estimated catch-at-age distribution for trawl-caught hake in the 2017–18 fishing year are in Table 5. The mean weighted CV of 14% was much lower than the target of 30%.

All estimated proportion-at-age-distributions from the WCSI trawl fishery are presented in Appendix A (Figure A4).

**Table 4: Numbers of measured male and female hake, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the WCSI trawl fishery.**

## 3.2 Trawl survey catch-at-age data for hake

### 3.2.1 Chatham Rise

Trawl survey catch-at-age distributions are estimates of the numbers of hake, by sex and age, available to the trawl in the survey area between 200 and 800 m. In some years additional deeper strata (800–1300 m) were surveyed. However, to ensure comparability, the distributions presented here are for the core strata only, i.e., 200–800 m.

Table 6 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The 30% target was met in only one of the 20 surveys (TAN9106, see Table 6). There was no survey of this area conducted in January 2019.

All estimated proportion-at-age distributions from the Chatham Rise trawl surveys are presented in Appendix A (Figure A5).

**Table 6: Numbers of measured male and female hake (used to calculate the catch-at-length and catch-at-age), age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Chatham Rise trawl surveys. Number of aged fish exceeds the number measured in some years, because hake caught outside the core trawl survey area were also aged.**

### 3.2.2 Sub-Antarctic

Trawl survey catch-at-age distributions are estimates of the numbers of hake, by sex and age, available to the trawl in the survey area. The main survey series was conducted in summer. Those surveys sampled depths from 300 to 800 m, plus an 800–1000 m stratum at Puysegur, and, in some years, other 800–1000 m strata off the Campbell Plateau. For comparability, the distributions presented here are for the core 300–800 m strata plus the deep Puysegur stratum only. The catch-at-age distributions from the spring and autumn surveys were derived from the core 300–800 m strata only.

Table 7 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. A catch-at-age distribution was not produced for the survey conducted in December 2016 (TAN1614) as only 33 hake were caught and it was not believed that they adequately represented the population. The details of the estimated catch-at-age distribution for hake caught in the December 2018 trawl survey are given in Table 8. The mean weighted CV of 52% did not meet the target of 30%.

All estimated proportion-at-age distributions from the Sub-Antarctic trawl surveys are presented in Appendix A; Figure A6 shows the summer survey distributions and Figure A7 shows the spring and autumn survey distributions.

**Table 7: Numbers of measured male and female hake (used to calculate the catch-at-length and catch-at-age), numbers of fish aged and used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age for the Sub-Antarctic trawl surveys. –, no data.**

### 3.2.3 West coast South Island

Trawl survey catch-at-age distributions are estimates of the numbers of hake, by sex and age, available to the trawl in the survey area. A combined trawl and acoustic survey by *Tangaroa* in winter 2000 (O'Driscoll et al. 2004) was replicated (with some modifications) in 2012 (O'Driscoll et al. 2014), 2013 (O'Driscoll et al. 2015), 2016 (O'Driscoll & Ballara 2018) and 2018 (O'Driscoll & Ballara 2019), so a five year comparable time series is available. The relative biomass estimates from the five surveys were standardised using random day-time bottom trawl stations in strata 1&2A, B, and C, and 4A, B, and C (depth 300–650 m, referred to as the ‘core’ strata), with stratum areas from the 2012 survey (O'Driscoll & Ballara 2018). Additional strata were sampled in the surveys from 2012 onwards, and the 2019 stock assessment of hake used biomass and catch-at-age series from an area combining the ‘core’ strata plus shallower waters from 200 to 300 m and deeper waters from 650 to 800 m (subsequently referred to as ‘all’ strata) (O'Driscoll et al. 2014).

Table 9 summarises the data used each year to produce the catch-at-age distributions for the ‘core’ and ‘all’ strata areas, and also lists the resulting mean weighted CVs. Because no otoliths from the 2000 survey were aged, the scaled length-frequency distribution from that survey was applied to the WCSI commercial fishery age-length key for 2000 to estimate a catch-at-age distribution. The age-length keys for the subsequent surveys were derived using otoliths collected during those surveys. The details of the estimated catch-at-age distribution for hake caught in the August 2018 trawl survey are given in Table 10. The mean weighted CVs of 60% (‘core’ strata) and 33% (‘all’ strata) did not meet the target of 30%.

All estimated proportion-at-age distributions from the WCSI trawl surveys are presented in Appendix A for the ‘core’ strata (Figure A8) and ‘all’ strata (Figure A9).

**Table 9: Numbers of measured male and female hake (used to calculate the catch-at-length and catch-at-age), age data used in the age-length key, tows sampled with a hake catch, and estimated mean weighted CV (%) by age for the ‘core’ strata (300–650 m) and ‘all’ strata (m) of the west coast South Island trawl surveys. See Section 2 for an explanation of why number aged is often larger than number measured.**

### 3.3 Observer catch-at-age data from ling longline fisheries

#### 3.3.1 Chatham Rise

The longline fishery data from the Chatham Rise were analysed using a single area stratum (i.e., FMAs 3 and 4 between 42° and 46° S), and a time stratum of 1 June to 31 October.

Table 11 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. There were no or insufficient data collected from the Chatham Rise ling longline fishery in 2010–2012. Four trips were observed in 2018, and the details of the estimated catch-at-age distribution are given in Table 12. The mean weighted CV of 26% met the target of 30%.

**Table 11: Numbers of measured male and female ling, age data used in the age-length key, trips and sets sampled, and estimated mean weighted CV (%) by age, for the Chatham Rise longline fishery.**

All estimated proportion-at-age distributions from the Chatham Rise longline fishery are presented in Appendix B (Figure B1).

### 3.3.2 Sub-Antarctic

The longline fishery data from the Sub-Antarctic stock were analysed as two separate fisheries, one spawning and one non-spawning. The spawning fishery was defined as a single stratum comprising the Puysegur Bank and Solander Corridor (i.e., Statistical Area 030), with a time stratum of 1 October to 31 December. The non-spawning fishery was defined as a single stratum comprising all of FMAs 5 and 6, excluding Statistical Area 030 and the Bounty Plateau, with a time stratum of 1 February to 31 July.

Ling on the Bounty Plateau were analysed separately from Sub-Antarctic ling because they are believed to comprise a distinct biological stock (Horn 2005).

Table 13 summarises the data used each year to produce the catch-at-age distributions for the two Sub-Antarctic longline fisheries, and also lists the resulting mean weighted CVs. Sufficient observer samples were available from the non-spawning fishery in the 2017–18 fishing year to produce a catch-at-age distribution (Table 14). The mean weighted CV of 21% was better than the target of 30%.

All estimated proportion-at-age distributions from the spawning and non-spawning Sub-Antarctic longline fisheries are presented in Appendix B (Figures B2 and B3).

**Table 13: Numbers of measured male and female ling, age data used in the age-length key, trips and sets sampled, and estimated mean weighted CV (%) by age, for the Sub-Antarctic spawning and non-spawning longline fisheries.**

Mean weighted CV (%), sexes pooled)			21.2	

### 3.3.3 West coast South Island

Longline fishery data from west coast South Island were analysed using a single area stratum and a time stratum of 1 May to 31 August.

Table 15 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The 2003, 2006 and 2007 age-length keys were developed using age data from the trawl fisheries in the same years, as no otoliths were sampled from longline trips. The 2006 and 2007 data were collected under the SeaFIC ling longline logbook programme (Langley 2001). The 2012 age-length key was developed using 129 otoliths sampled from a longline trip, plus additional age data from the July 2012 research trawl survey off WCSI. No longline trips targeting ling off WCSI were sampled in the 2017–18 fishing year. All estimated proportion-at-age distributions from the WCSI longline fishery are presented in Appendix B (Figure B4).

**Table 15: Numbers of measured male and female ling, age data used in the age-length key, trips and sets sampled, and estimated mean weighted CV (%) by age, for the west coast South Island longline fishery.**

Year	Males		Females		Trips	Sets	Mean CV
	Measured	Aged	Measured	Aged			
2003	123	215	148	246	3	24	37.9
2006	104	191	301	329	7	24	35.0
2007	109	119	192	169	7	28	42.2
2012	190	246	379	311	1	31	29.3
2015	296	144	188	97	2	49	29.5

### 3.3.4 Cook Strait

The longline fishery data from Cook Strait were analysed using a single area stratum (i.e., those parts of FMAs 2, 7, and 8 between 41° and 42° S and 174° and 175.4° E, equating approximately to Statistical Areas 016 and 017), and a time stratum of 1 June to 30 September.

Table 16 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The 2001 age-length key used 57 otoliths collected from the longline fishery (i.e., all that were collected), plus 316 otoliths collected from the trawl fishery in the same area and year. There was no observer sampling of Cook Strait longline-caught ling in the 2017–18 fishing year. All estimated proportion-at-age distributions from the Cook Strait longline fishery are presented in Appendix B (Figure B5).

**Table 16: Numbers of measured male and female ling, age data used in the age-length key, trips and sets sampled, and estimated mean weighted CV (%) by age, for the Cook Strait longline fishery.**

Year	Males		Females		Trips	Sets	Mean CV
	Measured	Aged	Measured	Aged			
2001	315	179	356	194	1	17	29.8
2003	165	164	145	142	1	31	33.1
2006	607	319	538	275	1	116	19.3
2007	238	125	180	92	1	43	33.8

### 3.3.5 Bounty Plateau

The longline fishery data from the Bounty Plateau were analysed using a single area stratum (i.e., that part of FMA 6 east of 176° E), and a time stratum of 1 November to 31 March.

Table 17 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. There were no data collected from the Bounty Plateau ling longline fishery in the 2017–18 fishing year. All estimated proportion-at-age distributions from the Bounty Plateau longline fishery are presented in Appendix B (Figure B6).

**Table 17: Numbers of measured male and female ling, age data used in the age-length key, trips and sets sampled, and estimated mean weighted CV (%) by age, for the Bounty Plateau longline fishery.**

Year	Males		Females		Trips	Sets	Mean CV
	Measured	Aged	Measured	Aged			
1992–93	201	52	237	69	1	24	50.4
1999–2000	1 102	106	2 184	185	1	41	26.9
2000–01	405	50	713	66	1	20	43.6
2003–04	1 155	200	1 628	300	3	272	20.0
2007–08	308	156	562	271	1	86	25.3
2008–09	262	116	213	88	1	42	37.3

### 3.4 Observer catch-at-age data from ling trawl fisheries

#### 3.4.1 Chatham Rise

Trawl fishery data from the Chatham Rise were used if they were collected between 1 October and 31 May in each fishing year, and were stratified using the following four strata:

1. Coast (longitude  $\leq 174^\circ$  E, target not scampi).
2. Scampi (all tows targeting scampi).
3. North Rise (latitude  $< 43.55^\circ$  S, longitude  $> 174^\circ$  E, target not scampi).
4. South Rise (latitude  $\geq 43.55^\circ$  S, longitude  $> 174^\circ$  E, target not scampi).

Scampi target tows were analysed as a separate stratum because the gear used in this fishery usually retains ling of a smaller average size than the trawls used to target finfish.

Table 18 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The estimated catch-at-age distribution for trawl-caught ling in the 2017–18 fishing year is given in Table 19. The observer sampling in 2017–18 was at a relatively low level, similar to the previous year but with more otoliths available. The mean weighted CV of 25% met the target value of 30%.

All estimated proportion-at-age distributions from the Chatham Rise trawl fishery are presented in Appendix B (Figure B7).

**Table 18: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Chatham Rise trawl fishery.**

### 3.4.2 Sub-Antarctic

Trawl fishery data from the Sub-Antarctic were used if they were collected between 1 September and 30 April in each fishing year, and were stratified using the following three strata:

1. Scampi (all tows targeting scampi).
2. Shallow (bottom depth  $\leq 450$  m, and target not scampi).
3. Deep (bottom depth  $> 450$  m, and target not scampi).

Table 20 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The estimated catch-at-age distribution for trawl-caught ling in the 2017–18 fishing year is given in Table 21. The mean weighted CV of 17% was lower than the target value of 30%.

All estimated proportion-at-age distributions from the Sub-Antarctic trawl fishery are presented in Appendix B (Figure B8).

**Table 20: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Sub-Antarctic trawl fishery.**

### 3.4.3 West coast South Island

Trawl fishery data off WCSI were used if they were collected between 1 June and 30 September each year, and were stratified using the following three strata:

1. Deep (bottom depth  $\geq 498$  m).
2. North shallow (bottom depth  $< 498$  m, latitude  $< 42.42^\circ$  S).
3. South shallow (bottom depth  $< 498$  m, latitude  $\geq 42.42^\circ$  S).

Table 22 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. There were insufficient data (particularly otoliths) collected to estimate the catch-at-age distribution for trawl-caught ling from 2009 to 2011. The details of the estimated catch-at-age distribution for trawl-caught ling in 2018 are given in Table 23. The amount of length data and otoliths available from that year was maintained at a relatively high level, as it has been since 2015. The mean weighted CV of 23% was lower than the target value of 30%.

All estimated proportion-at-age distributions from the WCSI trawl fishery are presented in Appendix B (Figure B9).

**Table 22: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the WCSI trawl fishery.**

Year	Males		Females		Tows	Mean CV

### 3.4.4 Cook Strait

The trawl fishery in Cook Strait was analysed using a single area stratum (i.e., those parts of FMAs 2, 7, and 8 between 41° and 42° S and 174° and 175.4° E, equating approximately to Statistical Areas 016 and 017), and a time stratum of 1 June to 30 September.

Table 24 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. There were insufficient data collected to estimate the catch-at-age distribution for trawl-caught ling in 2018 (350 length measurements, 162 otoliths).

All estimated proportion-at-age distributions from the Cook Strait trawl fishery are presented in Appendix B (Figure B10).

**Table 24: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Cook Strait trawl fishery.**

### 3.5 Trawl survey catch-at-age data for ling

#### 3.5.1 Chatham Rise

Trawl survey catch-at-age distributions are estimates of the numbers of ling, by sex and age, available to the trawl in the survey area between 200 and 800 m. In some years additional deeper strata (800–1300 m) were surveyed. However, to ensure comparability, the distributions presented here are for the core strata only, i.e., 200–800 m.

Table 25 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. There was no trawl survey of the Chatham Rise in January 2019.

All estimated proportion-at-age distributions from the Chatham Rise trawl surveys are presented in Appendix B (Figure B11).

**Table 25: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Chatham Rise trawl surveys.**

### 3.5.2 Sub-Antarctic

Trawl survey catch-at-age distributions are estimates of the numbers of ling, by sex and age, available to the trawl in the survey area. The main survey series was conducted in summer. Those surveys sampled depths from 300 to 800 m, plus an 800–1000 m stratum at Puysegur, and, in some years, other 800–1000 m strata off the Campbell Plateau. To ensure comparability, the distributions presented here are for the core 300–800 m strata plus the deep Puysegur stratum only. The catch-at-age distributions from the autumn surveys are derived from the core 300–800 m strata only.

Table 26 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. The details of the estimated catch-at-age distribution for ling caught in the December 2018 trawl survey are given in Table 27. The mean weighted CV of 25% was lower than the target of 30%.

All estimated proportion-at-age distributions from the Sub-Antarctic trawl surveys are presented in Appendix B; Figure B12 shows the summer survey distributions and Figure B13 shows the autumn survey distributions.

**Table 26: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age, for the Sub-Antarctic trawl surveys.**

### 3.5.3 West coast South Island

Trawl survey catch-at-age distributions are estimates of the numbers of ling, by sex and age, available to the trawl in the survey area. A combined trawl and acoustic survey by *Tangaroa* in winter 2000 (O'Driscoll et al. 2004) was replicated (with some modifications) in 2012 (O'Driscoll et al. 2014), 2013 (O'Driscoll et al. 2015), 2016 (O'Driscoll & Ballara 2018) and 2018 (O'Driscoll & Ballara 2019), so a five year comparable time series is available. The biomass estimates from the five surveys were standardised using random daytime bottom trawl stations in strata 1&2A, B, and C, and 4A, B, and C (depth 300–650 m, the ‘core’ strata), with stratum areas from the 2012 survey (O'Driscoll & Ballara 2018).

Table 28 summarises the data used each year to produce the catch-at-age distributions, and also lists the resulting mean weighted CVs. Because no otoliths from the 2000 survey were aged, the scaled length-frequency distribution from that survey was applied to the WCSI commercial fishery age-length key for 2000 to estimate a survey catch-at-age distribution. The age-length keys for the subsequent surveys were derived using otoliths collected during each survey. The details of the estimated catch-at-age distribution

for ling caught in the August 2018 trawl survey are given in Table 29. The mean weighted CV of 34% did not meet the target of 30%.

All estimated proportion-at-age distributions from the west coast South Island trawl surveys are presented in Appendix B (Figure B14).

**Table 28: Numbers of measured male and female ling, age data used in the age-length key, tows sampled, and estimated mean weighted CV (%) by age for the west coast South Island trawl surveys.**

## **4. DISCUSSION**

### **4.1 Hake**

In 2017–18 sufficient otoliths and length-frequency data to produce catch-at-age distributions that met the target mean weighted CV were available from the HAK 7 (WCSI, CV 14%) and the HAK 1 (Sub-Antarctic, CV 22%) fisheries. The target CV was met in most previous years for samples from the WCSI fishery (see Table 4). The sampling intensity in the WCSI commercial trawl fishery was relatively high in 2017–18, as it was in the previous five years (see Table 4). Sampling intensity in the Sub-Antarctic varied considerably between years, with consequent wide variation in the mean weighted CVs (see Table 2) but sampling for length-frequency data was moderate to high in all years since 2008–09. Sampling for otoliths was less intense than is desirable from 2013–14 to 2017–18 with only about 400 otoliths per year collected from the September–March fishery; a sample approximately twice this size would be desirable. Hake on Chatham Rise were analysed as two separate fisheries (see Table 1), but sampling intensity in both fisheries was low in 2017–18 and there were insufficient data to produce catch-at-age distributions. Sampling of the west Chatham Rise fishery resulted in catch-at-age distributions in all but one year from 1991–92 to 2010–11, but sampling intensity was low since then, and only two distributions were produced. Sampling of the east Chatham Rise fishery was sporadic since 1991–92, and only one distribution was produced since 2006–07.

The WCSI research trawl survey in August 2018 produced fewer measured hake from the core strata than in any other survey in the series (see Table 9); the 2018 sample size was only one-tenth that of the first survey in 2000. The mean weighted CV of 60% was much worse than the target of 30%; the target was met only in the first two surveys. The area surveyed by this series has increased over time (see O'Driscoll & Ballara 2019), but only the catch-at-age from the ‘core’ and ‘all’ strata areas are presented above. Catch-at-age data for the ‘core’ strata (300–650 m) in all surveys, for ‘all’ strata (200–800 m) in surveys since 2012, and for ‘deep’ strata (200–1000 m) since 2016 are presented by O'Driscoll & Ballara (2019) in a single comparison plot.

The Sub-Antarctic trawl survey in December 2018 produced a relatively low number of hake — only four surveys in the series had fewer numbers of hake measured from the core plus Puysegur strata (see Table 7). Consequently, the CV (52%) was much worse than the target of 30%. Females were markedly more abundant in the catch than males, as has occurred in most surveys in this series. The 2018 age distribution was similar in shape to the 2014 survey (see Figure A6).

On the Chatham Rise, younger hake tended to be concentrated in the west, with the population dominated by fish aged 2–10 years (see Appendix A, Figure A1). Middle-aged and older hake (i.e., 5–15 years old) tended to dominate catches in the east (see Figure A2). Previous analyses showed that males and females appeared to be about evenly abundant in all areas except Statistical Area 404, where males dominated the catch (Horn & Sutton 2009). Some year class progressions were apparent. The year class that spawned at the start of the 1990–91 fishing year (age 3 years in January 1994) appeared relatively strong, and was tracked in some subsequent distributions through to about 2003. There was a clear year class progression in the Chatham Rise survey distributions from 2004 to 2011 (Figure A5). The year class that spawned in late 2001 (aged 2+ years in January 2004) progressed through to age 9+ years in 2011, for both males and females.

In the Sub-Antarctic, there were some clear year class progressions, particularly in the male distributions. Figure A3 shows the progressions of hake aged 10 in 1990 through to age 16 in 1996, aged 6 in 1998 through to age 12 years in 2004, and age 5 in 2009 through to age 11 years in 2015.

The WCSI trawl catch was dominated by hake aged 5–12 years, with no clearly apparent year class progressions (see Figure A4). In some years, large numbers of 1- or 2-year-old fish were taken by the fishery, but these did not always manifest as strong cohorts in later years. The relatively abundant 2-year-old fish in catches from 2005, 2006, and 2007 progressed to comprise a high proportion of the catch from 2010 to 2012. Since 2011, fish older than 10 years appeared to be less abundant in the catch than in most previous years. The catch in most years since 2011 was dominated by males aged 5–7 years and

females aged 6–8 years. A characteristic of most of the WCSI distributions was that numbers of fish aged 3 and 4 years were generally very low. Fish of this age may be much less vulnerable or available to the trawl during the winter months of the fishery than younger or older hake.

## 4.2 Ling

Catch-at-age distributions were produced for the commercial longline fishery on the Chatham Rise in 2017–18, and the CV (26%) was below the 30% target. A distribution produced for the Sub-Antarctic longline non-spawning fishery in 2017–18 also met the CV target (21%).

Catch-at-age distributions were produced for trawl fisheries catching ling in three areas. The Chatham Rise distribution used observer length data applied to age-length keys obtained primarily from a trawl survey, i.e., Chatham Rise length data collected from October 2017 to May 2018 were applied to an age-length key comprised primarily of data from the January 2018 (TAN1801) trawl survey of Chatham Rise, but augmented with some observer-collected otoliths to cover lengths in the fishery data that were not sufficiently represented in the trawl survey samples. The estimated CV (25%) was better than the target value. Most samples in this series had CVs between 23 and 33%, and the level of observer sampling was reasonable in most years (see Table 18). The 2018 WCSI catch-at-age distribution was produced using commercial fishery length data applied to an age-length key derived primarily from the trawl survey conducted in the same area in August 2018 (TAN1807), but augmented with some observer-collected otoliths. The estimated CV (23%) was better than the target value. The 2017–18 Sub-Antarctic distribution used only observer length data and otoliths and had a mean weighted CV (17%) much better than the target of 30%. The CVs for this series in the last decade were all below 22%. The Sub-Antarctic and WCSI commercial fisheries were comprehensively sampled in 2017–18; sampling on the Chatham Rise was less intensive. An estimate of catch-at-age for the ling bycatch from the Cook Strait hoki spawning fisheries was not able to be produced for 2018 as insufficient fish were sampled. No age structure for the Cook Strait fishery has been produced since 2010.

Sufficient ling otoliths and length-frequency data were available from a trawl survey of the Sub-Antarctic (December 2018) to meet the mean weighted CV target (25%). The target was met in all of the previous surveys of this area (see Table 26). All available ling otoliths collected during the WCSI trawl survey in August 2018 were aged, but the mean weighted CV (34%) was still below the target of 30%. This is the worst result for this survey series (see Table 28); more intensive sampling for ling otoliths is recommended for future surveys.

The ling longline fisheries caught few fish younger than 7 years, and much of the catch was older than 12 years. Sex ratios of the longline catch were about 1:1 on the Chatham Rise and in Cook Strait, but were biased towards females in the other fisheries, particularly the Sub-Antarctic non-spawning fishery (see Figure B3). Clear year class progressions were not observed in any of the longline series.

Recruitment to the trawl fisheries was generally about two years earlier than to the longline fisheries (i.e., at about 5 years), and most of the catch was 13 years or younger. Some year class progressions were observed in some of the trawl series, particularly for female fish. On the Chatham Rise, a relatively strong year class of fish aged 5 in 2001 can be followed through to 2008 when they were 12 years old. Ling in the Sub-Antarctic aged 6 and 8 in 2002 were still relatively strong in 2006 at ages 10 and 12 years. Some similar patterns in Chatham Rise and Sub-Antarctic trawl survey catch-at-age were also observed, as would be expected given that the same age-length key was applied to trawl fisheries and trawl surveys from a particular area. In the Cook Strait trawl fishery, female ling exhibited a relatively strong year class aged 7 in 2001 through to age 11 in 2005.

The ling trawl catch-at-age distributions from the WCSI fishery often exhibited a trough at about age 6 or 7. This is consistent with an inflection point in the length-frequency distributions at lengths of about 72 cm for males and 77 cm for females (see figure 3 of Horn 2008a). Fish of this size may be less vulnerable or available to the trawl during the winter months of the fishery.

### 4.3 Observer sampling

All the commercial fishery catch-at-age distributions reported here were reliant on the collection by observers of length data and otoliths. It was noted above that some planned catch-at-age distributions could not be estimated owing to insufficient data being collected. In some situations, this has resulted from a marked reduction in effort in a fishery, e.g., the hake trawl fishery on the eastern Chatham Rise has produced relatively small catches since 2009–10 (Horn 2017). But for some fisheries, there was either insufficient or no observer sampling, or the observed trips occurred at times outside the ‘main’ fishery period used to estimate commercial catch-at-age. Sampling levels of trawl-caught ling off WCSI were low or inadequate in most years from 2006 to 2014, despite the presence of observers who comprehensively sampled hoki and hake from the same fishery that produces most of the ling catch. It appears likely that most observers were not aware of the need to comprehensively sample ling from the WCSI hoki target fishery (although this was rectified since 2015). If possible, it would be desirable to ensure that, for all fisheries where catch-at-age estimates are produced, sampled (observed) trips occur in the areas and months used to produce the time series reported here, and observers are adequately briefed on the sampling requirements. The areas and months for each fishery are listed in this document in the sections above, and are summarised below (Table 30).

**Table 30: List of hake and ling fisheries, showing the annual data sampling time periods that were used to produce the catch-at-age series presented above.**

Fishstock(s)	Area	Fishing method	Time period
HAK 1	Sub-Antarctic	Trawl	September–May
HAK 4 & HAK 1	Chatham Rise	Trawl	October–April
HAK 7	WCSI	Trawl	June–September
LIN 3 & LIN 4	Chatham Rise	Longline	June–October
LIN 5 & LIN 6	Sub-Antarctic	Longline spawning	October–December
LIN 5 & LIN 6	Sub-Antarctic	Longline non-spawning	February–July
LIN 6	Bounty Plateau	Longline	November–March
LIN 7	WCSI	Longline	May–August
LIN 2 & LIN 7	Cook Strait	Longline	June–September
LIN 3 & LIN 4	Chatham Rise	Trawl	October–May
LIN 5 & LIN 6	Sub-Antarctic	Trawl	September–April
LIN 7	WCSI	Trawl	June–September
LIN 2 & LIN 7	Cook Strait	Trawl	June–September

There are several important fisheries exhibiting current issues with the intensity of observer sampling. Issues were: 1) otolith sampling of ling and (particularly) hake in the Chatham Rise trawl fishery and hake from the WCSI trawl fishery was often inadequate to produce collections of otoliths that could be used to generate a comprehensive age-length key; and 2) negligible observer sampling of the WCSI ling line fishery which produces about 40% of the total WCSI ling catch but is seldom sampled by observers because the fishing trips tend to be of relatively short duration on small vessels. Our recommendations are as follows:

- Hake, Chatham Rise trawl: markedly increase the sampling of both lengths and otoliths (at least a four-fold increase is likely to be necessary).
- Hake, WCSI trawl: increase (e.g., double) the number of otoliths collected per sampled tow.
- Ling, Chatham Rise trawl: increase (e.g., by about 30%) the number of otoliths collected per sampled tow.
- Ling, WCSI longline: formulate an observer plan for this fishery that intensively samples both lengths and otoliths on any observed trips.

## 5. ACKNOWLEDGMENTS

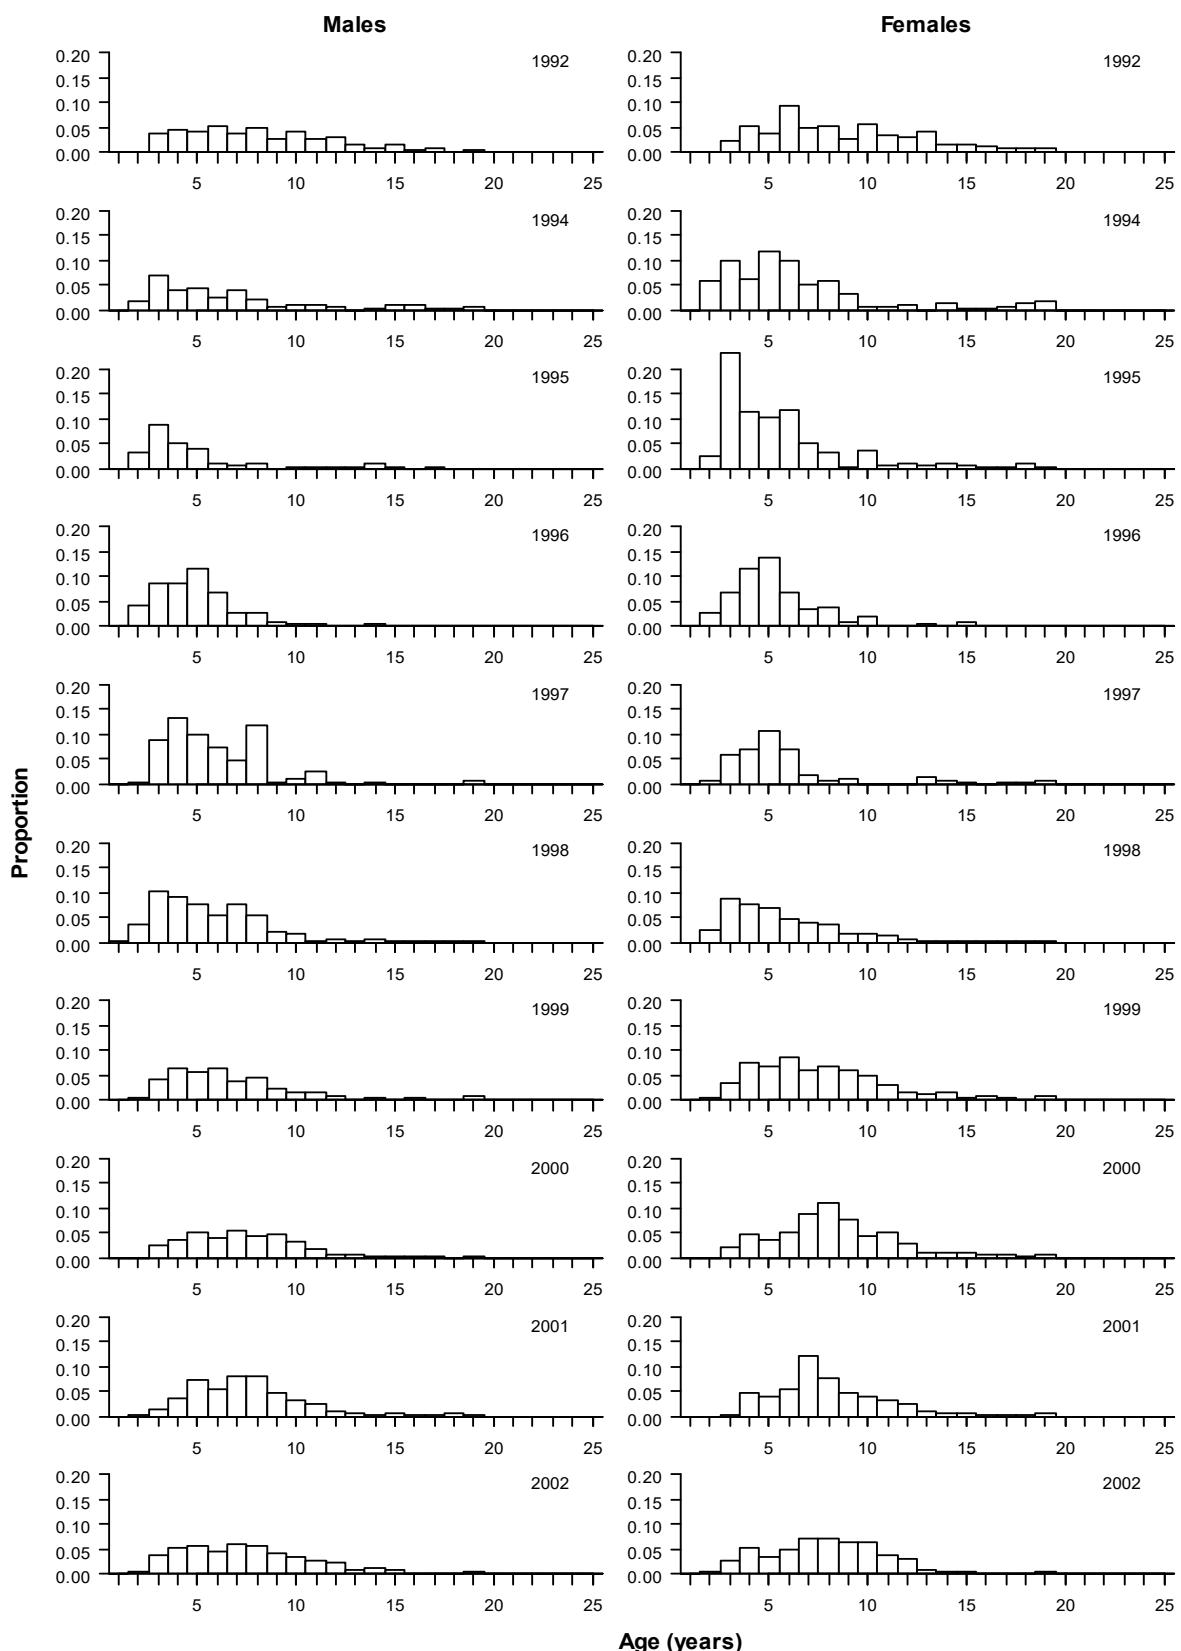

This work was funded by the Ministry for Primary Industries under Project MID201803. We thank Sira Ballara for the figures in Appendix C and Peter McMillan and Richard O'Driscoll for reviewing the manuscript.

## Appendix C: Observer sampling of hake from WCSI in 2017–18

The Deepwater Fisheries Assessment Working Group queried whether the observer sampling of hake in the WCSI fishery (HAK 7) in 2017–18 was representative of the fishery. Reported tow-by-tow landings of hake from the WCSI stock area were compared to the subset of those landings that were sampled for hake by observers. The analysis compared landings by month, statistical area, target species, and fishing method (Figure C1). All these categories were found to be comprehensively sampled in 2017–18 (i.e., 2018) as well as in all years since 2011. Most years before 2011 were also well sampled, although there was some under-sampling in June of some years.

**Figure C1: Comparison of estimated landed catch (grey filled circles) and observed catch (blue crosses), by fishing year (1989–90 to 2017–18), for HAK 7 by month, statistical area, target species, and fishing method. Circle area and cross width are proportional to estimated catch and observed catch, respectively, and sum to 1 across a year. Numbers on the right of the plots are the number of length-frequency samples taken each year.**

The WCSI hake fishery catch-at-age series used data from June to September. The analysis shown in Figure C2 compared landings by depth, week, and area (latitude and longitude). All these categories were found to be comprehensively sampled in 2018. Tows that targeted hake and hoki were well sampled, but tows that targeted ling (which produced about 10% of the hake landings) were not sampled. It was concluded that observer sampling satisfactorily represented the WCSI hake trawl fishery in 2018.

**Figure C2: Comparison of estimated landed catch (grey filled circles) and observed catch (blue crosses) for the period June to September 1990–2018, for HAK 7 by bottom depth, week, latitude, and longitude. Circle area and cross width are proportional to estimated catch and observed catch, respectively, and sum to 1 across a year.**
