## EXECUTIVE SUMMARY

## Dutilloy, A.; Horn, P.L.; Ó Maolagáin, C. (2020). Age composition of orange roughy from Cook Canyon (ORH 7B) in 2019.

New Zealand Fisheries Assessment Report 2020/29. 10 p.

Age frequencies were estimated for orange roughy (Hoplostethus atlanticus) from Cook Canyon (ORH 7B) using otoliths sampled from a 2019 acoustic survey. Otoliths ( $n=500$ ) were prepared and read by one reader following the accepted ageing protocol methods. The Cook Canyon aggregation had an age mode around 45 years, a relatively large group of fish over 100 years, and few younger fish.

## 1. INTRODUCTION

This report fulfils the reporting requirements relating to orange roughy (Hoplostethus atlanticus) for Objective 1 of Fisheries New Zealand project MID201902, "To determine catch-at-age for commercial catches and resource surveys of specified middle depth and deepwater fishstocks". The research in 201920 was the preparation and ageing of otoliths of orange roughy sampled from Cook Canyon (ORH 7B), from an acoustic survey conducted in June-July 2019 aboard FV Amaltal Mariner. These data enabled the estimation of ORH 7B age frequency for the 2019-20 fishing year, 13 years after the fishery had been closed. The derived age distribution will be used in the next ORH 7B stock assessment.

Recognising that orange roughy age estimates produced by New Zealand and Australian readers had poor comparability (Francis 2005, 2006, Hicks 2005), an Orange Roughy Ageing Workshop was held in 2007 to improve otolith preparation and zone interpretation between agencies. A revised protocol for ageing orange roughy was developed during the workshop (Tracey et al. 2007) and later this protocol was tested by two scientists from National Institute of Water and Atmospheric Research Ltd (NIWA) and two scientists from Fish Ageing Services Pty. Ltd. (FAS, Victoria, Australia). The revised ageing protocol solved the inter-agency between-reader problems and provided a consistent and documented method for the interpretation of growth zones in orange roughy otoliths for the region (Tracey et al. 2009, Horn et al. 2016).

The growth of juvenile orange roughy was validated by examining the otolith marginal increment type and by length frequency analysis (Mace et al. 1990). Later, Andrews et al. (2009) applied an improved lead-radium dating technique to orange roughy otolith cores, grouped by growth-zone counts from thin sections to validate age data. Results showed a high degree of correlation between the growth-zone counts and the expected lead-radium growth curve and provided support for both a centenarian life span for orange roughy and for the age estimation procedures using thin otolith sectioning.

### 1.1 The Cook Canyon fishery and relevant research

This fishery commenced in 1983 on an area near Cook Canyon in Statistical Areas 033, 034, and 705. Up to 1996-97, about $80 \%$ of catches were taken in winter (June-July) when orange roughy aggregate for spawning. The Total Allowable Commercial Catch (TACC) peaked at 1708 t between 1988-89 and 1994-95, was reduced in 1995-96, and reduced again in 2001-02 until the fishery was effectively closed from 1 October 2007 (with a TACC of 1 t ). Since 2015, a series of acoustic surveys have been conducted in Cook Canyon aimed at locating and surveying spawning plumes. In 2015, an orange roughy plume was identified. However, due to its transitory nature, the plume was not acoustically surveyed (Ryan \& Tilney 2016). In 2016, another acoustic survey was attempted, and, although a plume was identified, the survey was unsuccessful due to bad weather. In 2017, a successful acoustic survey was conducted on FV Amaltal Explorer, when the towed acoustic optical system (AOS) captured three snapshots of a single spawning plume in Cook Canyon, giving an average biomass estimate of 824 t (Ryan \& Tilney 2017). It was determined that the timing of the snapshots was late relative to the spawning cycle, because $40-50 \%$ of sampled fish had spent gonads (Ryan \& Tilney 2017).

The 2019 survey (Ryan \& Tilney 2019) marked the fourth acoustic biomass survey of orange roughy for Cook Canyon and was conducted from FV Amaltal Mariner. The average biomass estimate from the 2019 survey was 877 t . The age frequency from this survey was deemed suitable to be used in a stock assessment for the region, because it was considered to be representative of the spawning population.

## 2. METHODS

### 2.1 Ageing of orange roughy

Orange roughy otoliths were prepared using the NIWA preparation method described by Horn et al. (2016). One whole otolith from each of the selected fish was embedded in resin and cured in an oven. A thin section was cut along a line from the primordium (otolith nucleus region) through the most uniform posterior-dorsal axis using a sectioning saw with dual diamond-impregnated wafering blades separated by a $380 \mu \mathrm{~m}$ spacer. The section was mounted on a glass microscope slide under a glass cover slip.

All otoliths were read once by one experienced reader in accordance with the otolith interpretation and reading protocols described in the ageing methodology document (Horn et al. 2016). Although the ageing protocols suggest that two readers are the ideal, inter-agency calibrations continue at regular intervals between the NIWA and FAS scientists to ensure that there are on-going and consistent zone interpretations and no reader drift, so these single reader age readings were considered acceptable (P.L. Horn, NIWA, pers. comm.). The data produced include counts of zones from the primordium to the transition zone (TZ, the zone that marks the onset of orange roughy maturity, Francis \& Horn 1997) and from the TZ to the otolith margin, and readability codes for those readings provided on a 5-stage readability scale. Otolith data with a readability code of 5 (i.e., unreadable) for either the pre- or postTZ readings were excluded. The presence of a TZ was identified, ideally by the following three criteria: a clear reduction in zone width, a marked change in the optical density of the otolith from dark to light, and a change in curvature of the posterior arm of the otolith (Horn et al. 2016). TZs were classified using a 4 -stage scale, i.e.,

- 0 , not yet formed (or observed),
- 1, clear and unambiguous with all three criteria met,
- 2, a gradual transition with at least two criteria met,
- 3, a gradual transition with none or one of the criteria met.

For TZ classification 3, only a total age was recorded by the reader because the likely location of the TZ was undefined. Although pre- and post-TZ zone counts were recorded in the age determination of most otoliths examined, only the total age estimates were used in the analyses.

### 2.2 Survey design

The voyage was conducted from 26 June to 16 July 2019 in Cook Canyon using the FV Amaltal Mariner (Ryan \& Tinley 2019). The acoustic survey was designed to focus on the main spawning aggregation location as identified in the 2015, 2016, and 2017 surveys. Otoliths were randomly sampled by voyage scientists.

### 2.3 Analytical methods

### 2.3.1 Otolith selection

The method of analysis followed that of Dutilloy et al. (2019) for ORH 7A orange roughy. Otoliths were selected with replacement until a specified total number of unique otoliths ( $n_{\text {unique }}$ ) was reached. The procedure was continued to provide a selection of spare otoliths which were used to replace damaged or lost samples. The spares were used in the order of their selection. The selection probabilities for individual otoliths are proportional to the numbers of fish caught in each tow (or total orange roughy catch from the tow, if mean fish weights are similar across all tows) divided by the number of otoliths in the tow. This selection probability was based on all otoliths that were available and that the otolith sampling was random. If the same otolith was selected more than once, its age was repeated in estimating the mean age and age frequency. Since an age estimate may be used more than once, the number of ages, $n_{\text {ages }}$, is likely to be greater than the number of otoliths prepared, $n_{\text {unique }}$.

A total of 700 otoliths were sampled from the Cook Canyon spawning aggregation in 2019, of which a target of $n_{\text {unique }} 500$ otoliths were to be prepared and read, with a further 50 otoliths selected as spares. Preliminary orange roughy abundance estimates were derived by Ryan \& Tilney (2019).

### 2.3.2 Analysis

The data consisted of the age estimate from each otolith replicated by any repeat count. The mean age estimate was the sample mean. The age frequency was the fraction of data at each age over the entire age-otolith sample and was also estimated for each sex separately. Standard error was assessed using a bootstrap analysis where tows were resampled 500 times along with the ages within each selected tow.

Kernel smoothing was used to show the results in the plots. It used one parameter, width, which is approximately the moving window width over which the average age was calculated. This procedure used the 'density' function from the R statistical package (R Development Core Team 2014). Width was set to 10 .

## 3. RESULTS

The number of otoliths prepared and read from the 2019 survey samples was 500, but six otoliths were excluded because of a readability code of 5 . The station weights (i.e., relative population by station used to randomly sample otoliths) and otolith selection probabilities are listed in Appendix A (Table A1).

The sex-specific age frequency distributions are shown in Figure 1, based on data listed in Appendix B (Table B1, Table B2), and have different trends in age distribution. The male distribution is dominated by fish with ages ranging mainly from 20 to 65 years with a mean age of 51.5 years (19-138 years). The female age distribution is dominated by fish aged at between 30 and 65 with a mean age of 62.5 years (21-147 years).

Figure 1: Comparisons of the age frequency distributions by sex (females - red; males - black). The pairwise $\mathbf{9 5 \%}$ confidence limits are indicated by the shaded areas.

The overall, combined sexes age frequency distribution is shown in Figure 2, with data listed in Appendix B (Table B3). The distribution is dominated by middle-aged fish with ages ranging mainly from 30 to 65 years and a mode centred near 45 years. However, there was a relatively large number of fish aged over 100 years. The mean weighted CV was $15.4 \%$.

Figure 2: Estimated age frequency distribution (red bars) for Cook Canyon with a smoothed density through the age estimates (black curve).

## 4. DISCUSSION

Although otoliths have been routinely collected during research surveys of Cook Canyon, only those collected as part of the 2019 acoustic survey have been aged. This is due to otoliths collected in previous surveys being considered unrepresentative of the spawning population, either because they were sampled from a single tow in the spawning plume, or because sampling took place late in the spawning season. The 500 otoliths sampled in 2019 were taken from 6 tows targeting the spawning plume, with males and females being almost equally represented in each tow. However, the age distributions by sex were different, which may indicate: 1) different levels of exploitation, with males being more heavily exploited, 2) the area is considered transitory and the sexes do not arrive simultaneously, or 3) the fish were predominantly aggregating by sex and size, and the small number of tows did not comprehensively sample the population (Figure 2). Although the mode of the overall age frequency was around 45 years, there was a relatively large group that were aged at over 100 years (predominantly female), and few younger fish.

The data produced in this work could be used to provide estimates of productivity parameters for the Cook Canyon orange roughy population. It would be desirable to use growth parameters specifically applicable to these fish in stock assessments. The available data on age at the formation of the otolith transition zone would also enable age at maturity to be re-estimated using data produced following the revised age determination protocol.

## 5. ACKNOWLEDGMENTS

This work was funded by the Fisheries New Zealand under Project MID201902. Thanks to Ian Doonan for advice, and Richard Saunders for useful reviews of the document.
