EXECUTIVE SUMMARY

Saunders, R.J.; Horn, P.L.; Ó Maolagáin, C. (2021). Age data of orange roughy (*Hoplostethus atlanticus*) from the northwest Challenger region in 1993, 2013, and 2018.

New Zealand Fisheries Assessment Report 2021/39. 28 p.

This report describes the age data from samples of the commercial catch of orange roughy (*Hoplostethus atlanticus*) taken from the northwest Challenger region (outside New Zealand's Exclusive Economic Zone) in 1993, 2013, and 2018. Orange roughy were aged from thin sections of sagittal otoliths according to the protocol developed at the orange roughy ageing workshop in 2007. The median age of adult orange roughy was lower in 2018 than in 1993 and the change in median age was greater for males than females. Estimated age at maturity, based on the timing of formation of the transition zone, was 27 years for both sexes. Age estimates ranged from 17 to 162 years.

1. INTRODUCTION

This report fulfils the reporting requirements relating to orange roughy (*Hoplostethus atlanticus*) for Objective 2 of Project MID201902, “Routine age determination of middle depth and deepwater species from commercial fisheries and resource surveys” and was funded by Fisheries New Zealand. The objective required the preparation and ageing of otoliths of orange roughy sampled from the northwest Challenger region, to the west of New Zealand (Figure 1), from the years 1993, 2013, and 2018. This region is outside the New Zealand Exclusive Economic Zone (EEZ) and the orange roughy fishery is managed via the South Pacific Regional Fisheries Management Organisation (SPRFMO). Orange roughy from northwest Challenger are considered to be a separate stock from those landed in fisheries operating in the southwest Challenger and Lord Howe Rise (Clark et al. 2016).

A protocol for ageing orange roughy was developed during an international workshop in 2007, and a formal documentation of this protocol was produced by Horn et al. (2016). The growth of juvenile orange roughy has been validated by examining the otolith marginal increment type and by length frequency analysis (Mace et al. 1990). Andrews et al. (2009) applied a lead-radium dating method to orange roughy and showed a reasonable correlation of the growth-zone counts to the expected lead-radium growth curve. This work provided support for both a centenarian life span for orange roughy and for the age estimation procedures using thin otolith sectioning (Horn et al. 2016).

The aim of the work was to generate a set of age data from samples collected in 1993, 2013, and 2018 by New Zealand’s Scientific Observer Programme. These are the first substantial sets of age data produced for orange roughy from this area.

2. METHODS

All fish catch data and otoliths used in this analysis were collected by New Zealand Ministry for Primary Industries (MPI) observers aboard commercial fishing trawlers. Observers are directed to extract otoliths from a random sub-sample of fish. The number of otoliths collected from each tow has varied over the period of the Observer Programme but for the tows used in this work otolith numbers ranged from 2 to 23 with an average of 9. Otoliths sampled from fishing that occurred from June to July in the Northwest Challenger SPRFMO Bottom Trawl Management Area (Figure 1) were selected for preparation. All available otoliths from this time period were used in the analysis as directed by MPI (see Cordue 2020). An additional set of otoliths was also prepared from May 1993 because there were low numbers of available otoliths from the June-July period in that year (Table 1).

Orange roughy otoliths were prepared using the NIWA preparation method described by Horn et al. (2016). One whole otolith from each of the selected fish was individually embedded in resin and cured in an oven. A thin section was cut along a line from the primordium (otolith nucleus region) through the most uniform (and usually the longest) posterior-dorsal axis using a sectioning saw with dual diamond-impregnated wafering blades separated by a 380 µm spacer. The section was mounted on a glass microscope slide under a glass cover slip. When collected, some otoliths had been damaged such that the tips of the posterior-dorsal axes were missing on both otoliths. In some situations, however, it was possible to take sub-optimal, but complete, sections at other locations on the posterior-dorsal axis. For some sampled fish, both otoliths were too damaged or incomplete, and consequently neither otolith was prepared.

All otoliths were read once by one reader using the otolith interpretation and reading protocols described in the ageing methodology document (Horn et al. 2016). The data produced include counts of zones from the primordium to the transition zone (TZ, the zone that is considered to mark the onset of orange roughy maturity; Francis & Horn 1997), and from the TZ to the otolith margin, and readability codes for those readings provided on a 5-stage readability scale (Horn et al. 2016). Otolith data with a readability code of 5 (i.e., unreadable) for either the pre- or post-TZ readings were excluded. The presence of a TZ was identified, ideally, by the following three criteria: a clear reduction in zone width,

a marked change in the optical density of the otolith from dark to light, and a change in curvature of the posterior arm of the otolith (Horn et al. 2016). The TZs were classified after Horn et al. (2016) using a 4-stage scale, i.e.:

- 0, not yet formed (or observed),
- 1, clear and unambiguous with all three criteria met,
- 2, a gradual transition with at least two criteria met,
- 3, a gradual transition with none or one of the criteria met.

For TZ classification 3, only a total age was recorded by the reader because the likely location of the TZ was undefined.

Prior to reading the otoliths the reader (Richard Saunders) read a set of 160 otoliths with agreed ages and achieved a CV of 5.3% for total age and 5.9% to age at transition. There was slight bias in total age by on average 1.3 years. These are well within acceptable limits identified in the ageing methodology (Horn et al. 2016).

2.1 Data presentation

Unscaled age frequency distributions by sex were made using one-year and five-year bins. Summary statistics were calculated by sex for total age and age to the TZ when one was recorded.

3. RESULTS

The number of otoliths available varied by month and year with greater numbers available in 2018 than in the earlier years (Table 1). The proportion of otoliths unsuitable for preparation was highest in 1993 at 31% but much lower in the two most recent years at 13% and 7%, respectively (Table 1). Very few of the remaining otoliths resulted in failed preparations (7 of 1126). There were 14, 27, and 26 unreadable otoliths in each year, respectively (readability code 5). Age estimates ranged from 17 to 162 years (Table 2). The median and mean ages were highest for both sexes in the 1993 fish compared with the 2013 and 2018 fish (Table 2). A greater difference in median age over the years was observed for males than females (Table 2, Figures 2, 3, & 4). Mean age at the transition zone (i.e., age at maturity, see Francis & Horn (1997)) was 27 for both males and females but varied widely (Table 3). Raw age data are provided in Appendix A.

4. DISCUSSION

Age data were produced for orange roughy from commercial fishery samples from the northwest Challenger region. These data constitute the first available substantial collection of age information for orange roughy in the area.

There is a clear difference in the unscaled age frequency distributions between the sampled years, with the main difference being a marked reduction in the relative numbers of large males in recent (2018) samples compared with earlier samples (1993). This observation corresponds with other recent age frequency estimates of orange roughy on the central Louisville Ridge which contrasted 1995 and 2013–15 (Horn & Ó Maolagáin 2019). The lower median age for males in contrast to females in the most recent year (2018) was also observed for the Louisville population in 2013–15 (Horn & Ó Maolagáin 2019) and more recently inside the New Zealand Exclusive Economic Zone in ORH 7B for June–July of 2019 (Moore et al. in prep).

The reasons for the temporal changes in the age frequencies observed here are uncertain. They could be a real effect on the population composition as a consequence of fishing but could also be driven by the

less comprehensive sampling in 1993 and the inclusion of the May sample in that year. Although the trends observed are strong, it should be noted that the age frequencies presented in this report are unscaled. A more detailed analysis of age frequency data in other years, and/or further ageing investigations, could provide an understanding of this issue.

The estimated age at maturity of 27 years, based on age at transition zone formation, corresponded well with those for New Zealand mainland stocks (26–29 years, Horn et al. 2016). This was slightly lower than that observed for another stock outside the New Zealand EEZ, at the central Louisville Ridge, at 31 years (Horn & Ó Maolagáin 2019).

5. ACKNOWLEDGMENTS

We thank Jane Halliday (NIWA) for assistance with otolith section preparation, and Adele Dutilloy and Jeremy McKenzie (NIWA) for reviewing the manuscript. This work was funded by Fisheries New Zealand under project MID201902.
